HEALTHY SOIL BUILDING FOR BEGINNERS

OVERVIEW:

- 1. Soil and plant nutrition basics
- 2. Six soil health principles
- 3. Soil Structure

SOIL AND PLANT NUTRITION BASICS

 It is really not possible to talk about soil health without talking about plants and soil biology - everything is connected!

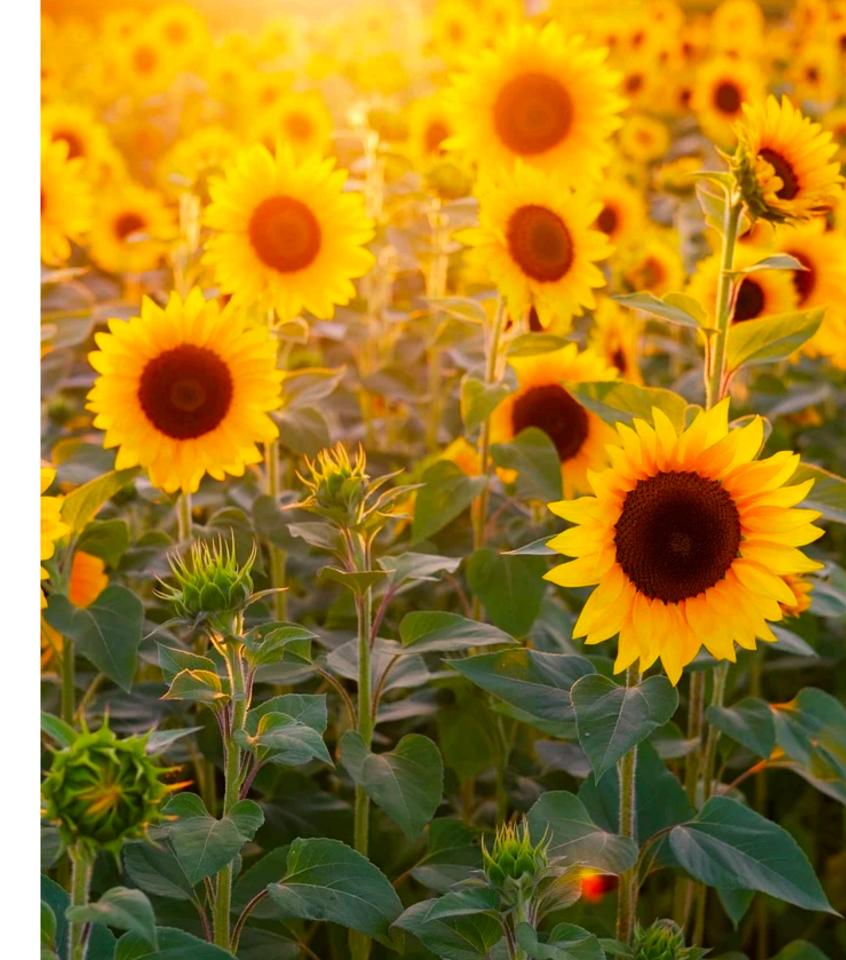

- 1. The Sun! It all starts far from the soil and from this earth.
 - Light from the sun is what drives plant nutrition, soil health and life on earth!
 - 2. In Photosynthesis, the plant uses energy from the sun along with CO2 and H2O, to produce sugars (liquid carbon).

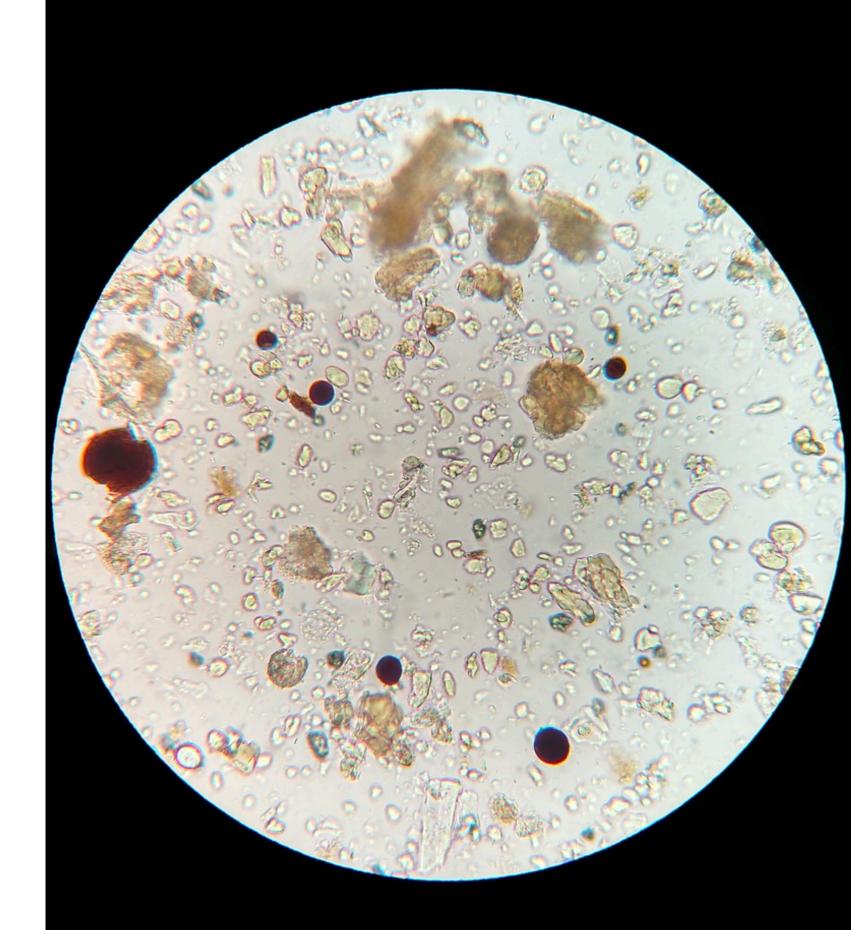

1. Liquid Carbon Pathway

- 1. Plants take in CO2 and H2O
- 2. Photosynthesis occurs, using energy from the sun
- 3. Oxygen and carbohydrates (liquid carbon) are produced
- 4. A portion of this "liquid carbon" is moved to the roots
- 5. And exuded from the roots into the soil

- 1. A large portion of exudate is consumed by microbes
- 2. And part of it combines with water to form carbonic acid
 - 1. This mild acid breaks down rocks and organic matter
 - 2. Making nutrients available for consumption by soil microbes

- The Rhizosphere a thin, exudate rich, film that surrounds roots and has a heavy microbial population. We will highlight three types of microbes that operate in the rhizosphere:
 - 1. Mycorrhizal Fungi
 - 2. Diazotrophs
 - 3. Heterotrophs

- Mycorrhizal Fungi form symbiotic relationships with plant roots
 - 1. Extend the reach of roots through mycelial hyphae expanding the rhizosphere into the mycorrhizosphere.
 - 2. This increased surface area comes into contact with up to 100 times more soil.

- 1. Healthy populations of Mycorrhizal fungi have been shown to:
 - Increase availability of nutrients to plants
 - 2. Improve drought tolerance
 - 3. Increase pest and disease resistance
 - 4. Speed up development of plants/fruits
 - 5. Increase quantity of flowers/fruits

- Diazotrophs microorganisms, mostly bacteria, that fix nitrogen from the air and convert it into forms usable by soil organisms and plant roots. There are two primary categories of diazotrophs:
 - 1. Symbiotic diazotrophs
 - 2. Free-living diazotrophs

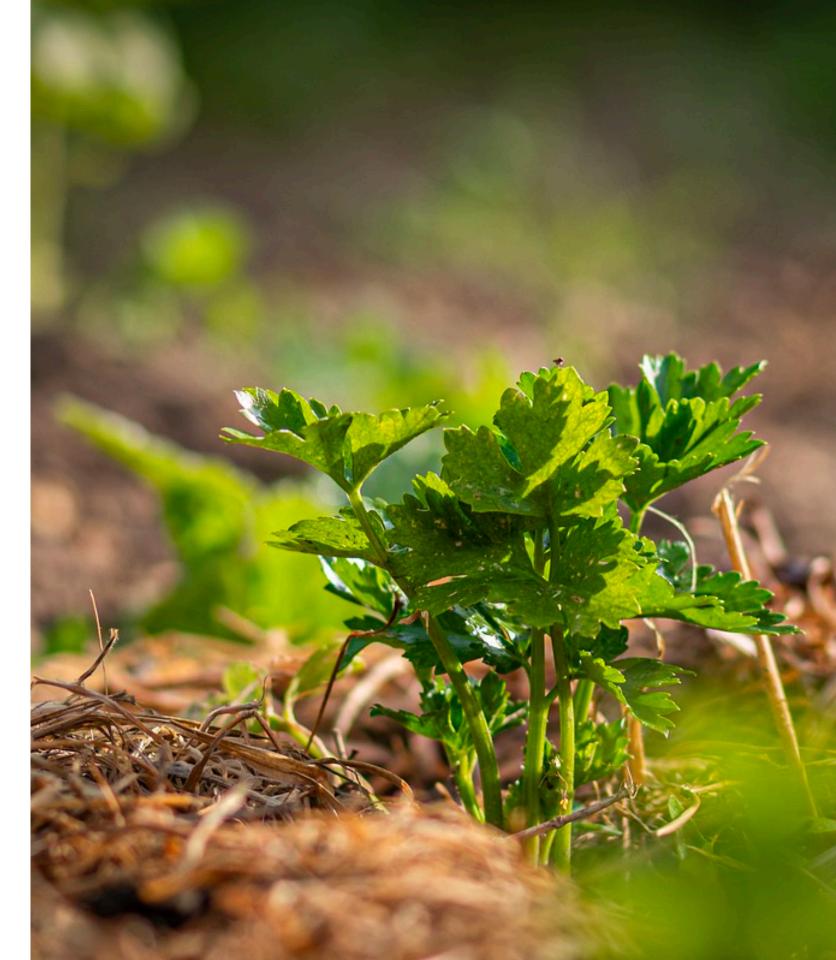

- 1. Diazotrophs slow N fixation or shut it down altogether when:
 - 1. Synthetic Nitrogen is added to the soil
 - 2. Soil contains excess levels of O, as is the case after tillage

1. **Heterotrophs** - organisms that cannot produce their own energy. This category includes many bacteria and fungi, as well as nematodes, insects, mollusks, earthworms and animals.

- All heterotrophs require the fuel that is originally supplied by photosynthesis.
- 2. The soil heterotrophs thrive best in undisturbed soil that is covered in plant material.
- 3. Among heterotrophs, there are decomposers, predators and prey, aerators and mixers, all comprising the diversity that keeps nature balanced.

SIX SOIL HEALTH PRINCIPLES

- 1. Environment what you are "given"
 - 1. Latitude (daylight hours)
 - 2. Seasonal patterns
 - 3. Temperature patterns (USDA plant hardiness zone)
 - 4. Wind patterns (prevailing winds, weather)
 - 5. Rainfall (overall and dispersal through the year)
 - 6. Natural flora and fauna
 - 7. The "lay" of the land (orientation, slope, drainage)
 - 8. Soil type, composition

1. Resources - what you "have"

 Economic - capital, income sources and amounts, markets, access to markets

2. Physical - tools, equipment, infrastructure

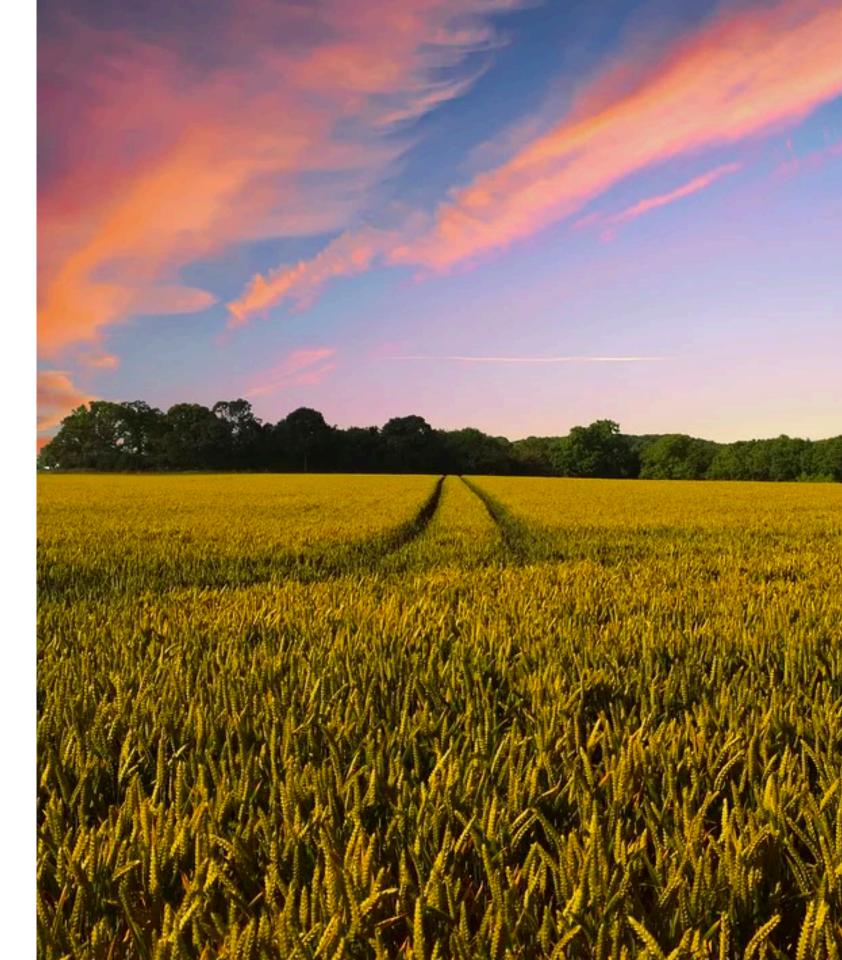

- 1. Community
 - 1. Family
 - 2. Neighbors
 - 3. Social groupings (church, social clubs, work/business associates & associations, political affiliations)
 - 4. Government (city, county, state, nation)

- 1. Spiritual/Philosophical Your Worldview
 - 1. Faith in the Creator
 - 2. Faith in the creation (how He created it to be and function).
 - 3. Informs our worldview and colors how we see all things

- Good decision making requires a good understanding of our context.
- 2. The context will be different for each and every person, home, garden or farm.

2: MINIMAL DISTURBANCE

- 1. Both mechanical and chemical
- 2. What tillage can do to soil structure
 - 1. Tillage destroys soil structure
 - 2. Tillage reduces water infiltration
 - 3. Tillage reduces organic matter
 - 4. Tillage increases weeds

3: ARMOR (MULCH)

4: DIVERSITY

5: LIVING ROOTS IN THE SOIL

6: ANIMALS

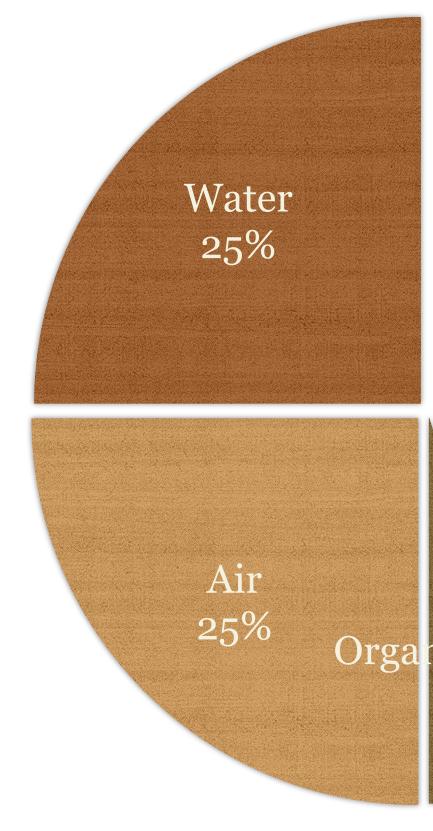

SOIL STRUCTURE

SOIL COMPOSITION CHART

- Each component plays a significant role.
- Soil health and fertility is a function of all these components in relationship and much more.

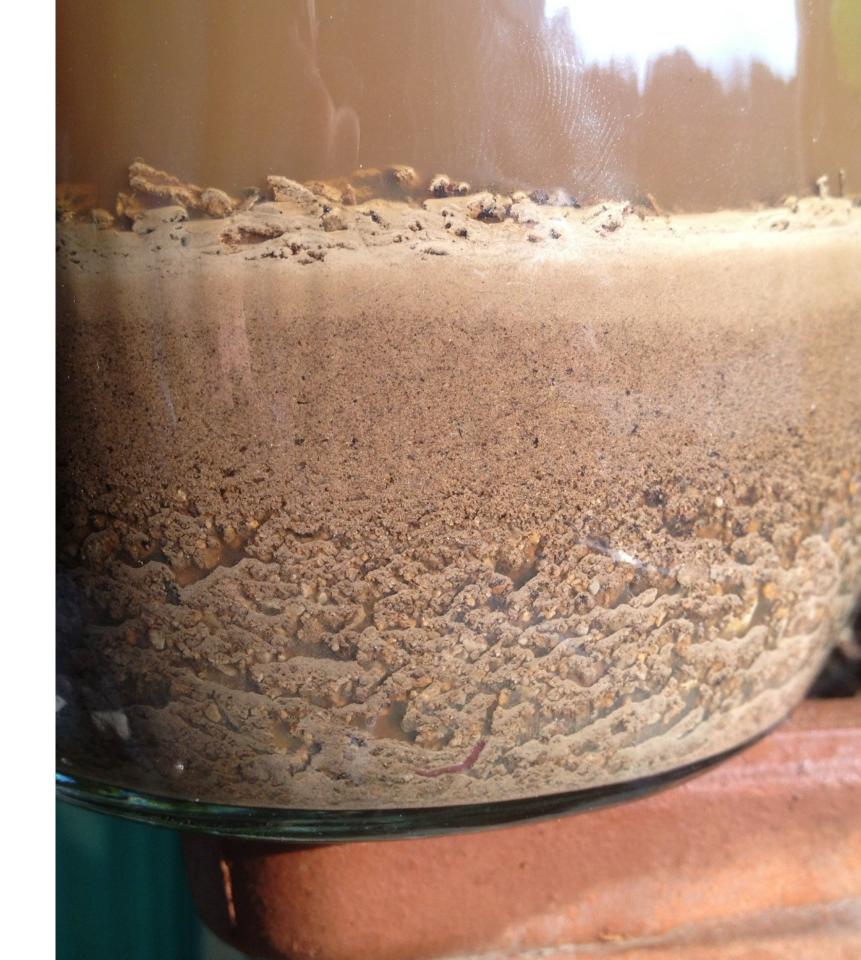

Minerals 45%

Organic Matter 5%

MINERALS

- 1. Minerals traditional soil science has focused here
 - 1. Clay
 - 2. Silt
 - 3. Sand
 - 4. Mineral soil nutrients

THE BASICS

1. Let's compare sizes for fun

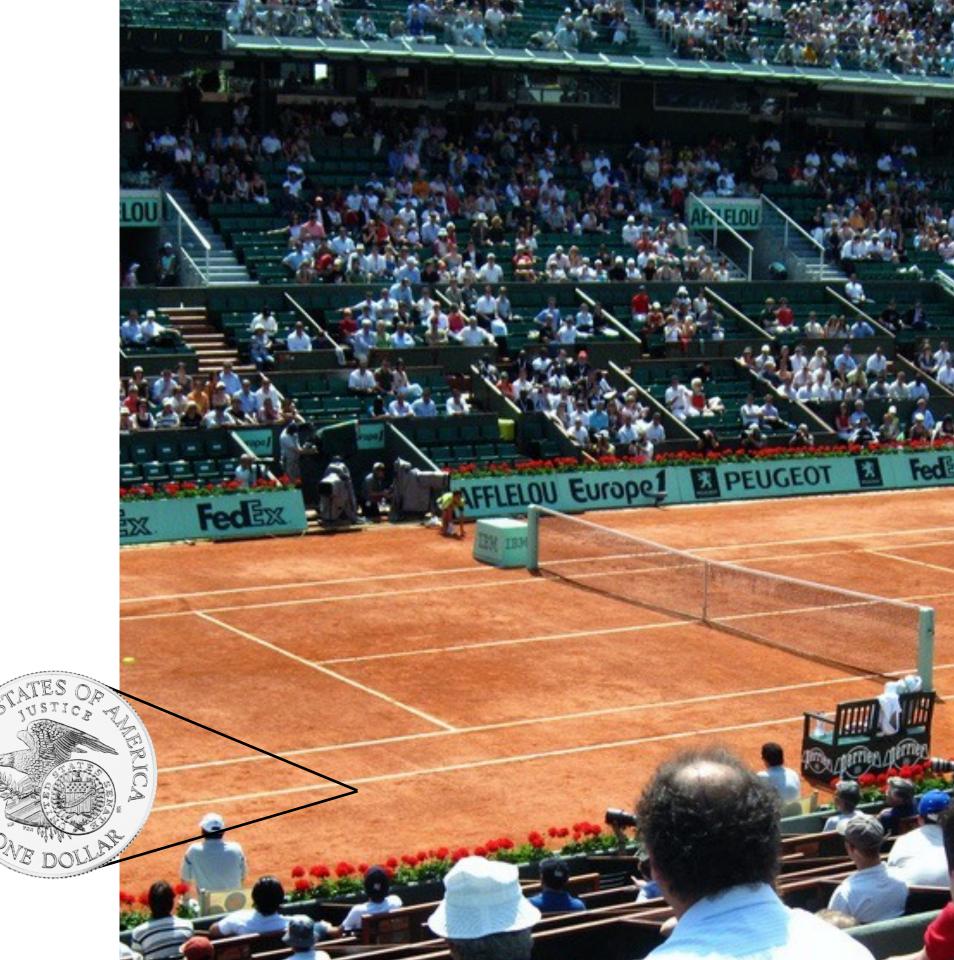

- 1. If clay were the size of a beet seed
- 2. Silt would be about the size of a beet
- 3. Sand would be a wheelbarrow

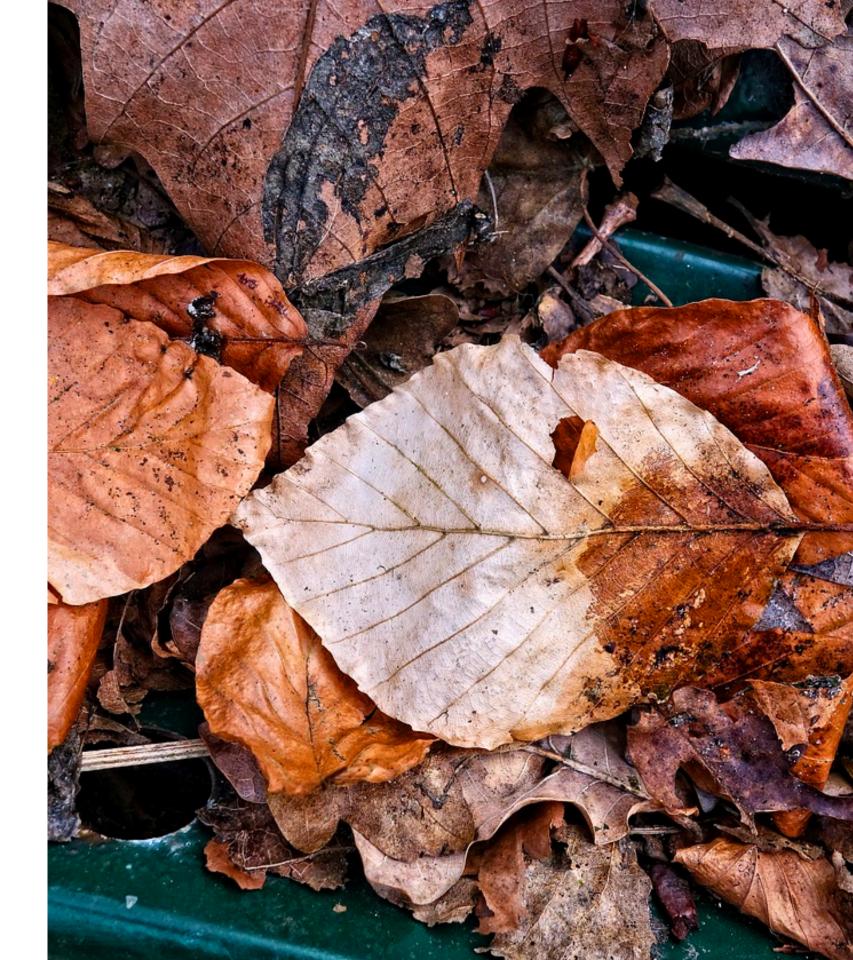

THE BASICS

- Or: a teaspoon of sand spread one particle deep would cover about the space of silver dollar
- 2. Whereas clay could cover a tennis court and possibly more

ORGANIC MATTER

- 1. Organic Matter
 - 1. Dead plant debris (leaves, sticks, roots, etc.)
 - 2. Dead soil creatures (including microbes)
 - 3. Living plant material mostly roots
 - 4. Living creatures, protozoa, bacteria and fungi

AIR & WATER

1. Pore Spaces

- 1. Essential for air and water movement in soil
- 2. Why are air and water necessary?
- 3. What creates pore space?
 - 1. Sand and gravel in the soil
 - 2. The activity of soil creatures (worms, ants, others)
 - 3. Aggregates

AIR & WATER

1. Aggregates

- Aggregates are minerals and organic matter bound together in clumps that vary in size and shape.
- 2. Soil aggregates are a key, visible indicator of soil health

HOW AGGREGATES ARE DESTROYED

1. Tillage destroys soil structure by:

- 1. Breaking up soil aggregates
- 2. Aggregates provide "structure" to soil, which:
 - Increase porosity of soil for better air and water movement in soil
 - 2. Increases water infiltration and retention
 - 3. Reduce runoff and erosion

HOW AGGREGATES ARE FORMED

- 1. Aggregates are formed by the life in the soil.
 - 1. Plant roots exudates
 - 2. Around organic matter (by bacterial and fungal decomposers) polysaccharide "glues"
 - 3. The activity of earthworms
 - 4. Mycorrhizal fungi play a star role in the development of soil aggregates.
 - 1. Fungal hyphae
 - 2. Glomalin produced by fungal hyphae

INCREASING MYCORRHIZAL FUNGI

- 1. Ways to increase Mycorrhizal fungi
 - 1. Reduce/eliminate chemical usage
 - 2. Reduce/eliminate tillage
 - 3. Reduce/eliminate synthetic fertilizers
 - 4. Keep living roots in the soil as much as possible
